

Objective

This example demonstrates how to write to the flash memory of a PSoC® 6 MCU device. In this example, the flash write API function blocks the caller until the write is completed.

Requirements

Tool: PSoC Creator™ 4.2 with PDL 3.0.4

Programming Language: C (ARM® GCC 5.4.1 and ARM MDK 5.22)

Associated Parts: All PSoC 6 MCU parts

Related Hardware: CY8CKIT-062-BLE PSoC 6 BLE Pioneer Kit

Overview

This example writes a flash row using a Peripheral Driver Library (PDL) API function. The function blocks the caller until the write is completed.

Hardware Setup

This example uses the CY8CKIT-062-BLE kit's default configuration. Refer to the kit guide to ensure that the kit is configured correctly.

This example uses a green LED to indicate the successful flash write operation; the LED does not operate at 1.8 V. By default, the kit is configured to operate at 3.3 V.

Software Setup

None.

Operation

1. Plug the CY8CKIT-062-BLE kit board into your computer's USB port.
2. Build the project and program it into the PSoC 6 MCU device. Choose **Debug > Program**. For more information on device programming, see PSoC Creator Help. Flash for both CPUs is programmed in a single program operation.
The green LED turns ON if the flash write is successful.
3. Set the value of the macro MAKE_FLASH_WRITE_FAIL in the *main_cm4.c* file to '1', program the device, and observe that the red LED turns ON to indicate that the flash write operation failed.

Design

In this example, the ARM® Cortex®-M0+ core (CM0+) simply enables the Cortex-M4 core (CM4) and enters Deep Sleep. The CM4 core executes the implementation of this example.

The example uses a constant array with size equaling the size of one flash row. The main function places the contents of the array in the flash at an address such that it occupies one complete flash row, by calling the flash write API function. It then verifies the flash data by comparing the flash data with the written data. If the flash write is successful, the green LED turns ON. Otherwise the red LED turns ON.

This example uses the PDL function that blocks the caller until the flash write operation is completed. The PDL also provides functions to perform flash write in a non-blocking manner using the hardware interrupt from the flash block. See [CE221122 – PSoC 6 MCU Non-blocking Flash Write](#) for details.

Components and Settings

Table 1 lists the PSoC Creator Components used in this example, how they are used in the design, and the non-default settings required so they function as intended.

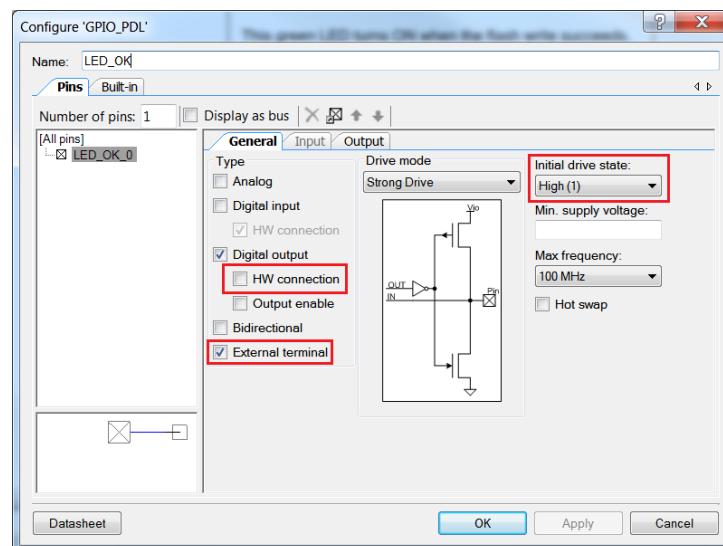

Table 1. PSoC Creator Components

Component	Instance Name	Purpose	Non-default Settings
Digital Output Pin	LED_OK	Provides visual feedback	See Figure 1
Digital Output Pin	LED_ERROR		

For information on the hardware resources used by a Component, see the Component datasheet.

Figure 1 highlights the non-default settings for the LED_OK instance of the Digital Output Pin Component. This setting also applies to the other instance of the Component, LED_ERROR.

Figure 1. Digital Output Pin Configuration

Reusing This Example

This example is designed for the supported kit(s). To port the design to a different PSoC 6 MCU device and/or kit, change the target device using the Device Selector and update the pin assignments in the **Design Wide Resources Pins** settings as needed. For single-core PSoC 6 MCU devices, port the code from *main_cm4.c* to *main.c*. If you change the device or design, you may need to adjust the source files that come with the example. These are not automatically generated and may not work with a modified design.

In some cases, a resource used by a code example (for example, an IP block) is not supported on another device. In that case the example will not work. If you build the code targeted at such a device, you will get errors. See the device datasheet for information on what a particular device supports.

This code example uses a green LED to indicate the successful flash write operation; the LED does not operate at 1.8 V.
